PROCESS TO CONTINUOUSLY PREPARE TWO OR MORE BASE OIL
GRADES AND MIDDLE DISTILLATES

Field of invention

The invention relates to a process to continuously prepare two or more base oil grades and middle distillates.

5 Background of the invention

WO-A-0250213 describes a process wherein different base oil grades are made in a so-called blocked out mode. In this process a bottoms fraction of a fuels hydrocracking process, which thus also yields middle
10 distillates as products, is separated into various base oil precursor fractions. These fractions are subsequently catalytically dewaxed one after the other using a platinum-ZSM-5 based catalyst.

WO-A-9718278 discloses a process wherein up to 4 base
15 oil grades, e.g. a 60N, 100N and 150N, are prepared starting from the bottoms fraction of a fuels hydrocracker. In this process the bottoms fraction is fractionated in a vacuum distillation into 5 fractions of which the heavier 4 fractions are further processed to
20 different base oil grades by first performing a catalytic dewaxing followed by a hydrofinishing step.

A disadvantage of the above processes is that the process is not continuous. In other words the base oil grades are not made at the same time but sequential. This
25 requires tankage for the intermediate products as obtained when the hydrocracker bottoms are fractionated and are awaiting their turn to be catalytically dewaxed. A further disadvantage are the mode switches which result in heating up of equipment and cooling of equipment

causing erosion of equipment. The mode switches also result in intermediate off-spec product every time a new grade is being processed. These slops need to be reprocessed or disposed off which is disadvantageous.

5 EP-A-649896 discloses a process to prepare a residue comprising a base oil by means of a process involving a hydrotreating step and a hydrocracking step on a heavy petroleum feedstock. The hydroprocessing steps yield a product from which middle distillates and a bottoms
10 fraction (residue) are obtained. This bottoms fraction is subsequently solvent dewaxed to a single base oil grade.

 WO-A-9723584 discloses a process wherein the bottoms fraction of a fuels hydrocracker is subjected to a catalytic dewaxing step. The dewaxed oil is partly
15 recycled to the hydrocracking step and partly obtained as the lubricating base oil.

 A disadvantage of the above process as described in WO-A-9723584 is that if more than one base oil grade is isolated from the dewaxed oil a large pour point
20 distribution occurs. In other words the resulting lower viscous base oil grades will have a too low pour point. This pour point give away, or difference with the desired value, is indicative for yield loss of said lower viscous base oil grade.

25 The object of the present invention is to provide a process, which is capable of preparing two or more base oil grades simultaneously and wherein their respective pour points are more close to the desired values.

Summary of the invention

30 The following process provides a solution to the above-described problem. Process to prepare simultaneously two or more base oil grades and middle distillates from a de-asphalted oil or a vacuum distillate feed or their mixtures by performing the
35 following steps:

- (a) hydrocracking the feed,
(b) distillation of the effluent as obtained in step (a) into one or more middle distillates and a full range residue boiling substantially above 340 °C,
5 (c) separating, by means of a further distillation step said full range residue into a light base oil precursor fraction and a heavy base oil precursor fraction,
(d) reducing the pour point of each separate base oil precursor fraction in two simultaneously and
10 parallel operated catalytic dewaxing reactors,
(e) hydrotreating the dewaxed oil as obtained when dewaxing the heavy base oil precursor fraction,
(f) isolating from the dewaxed oil from the light base
15 oil precursor fraction from step (d) and the hydrotreated oil from step (e) two or more base oil grades.

Applicants found that when processing according to the invention it is possible to continuously prepare two
20 or more base oil grades and at the same time reduce the hydrotreating capacity because only the heavier grades which require further hydrotreating are subjected to said step (e). Further any product give away in pour point may be avoided because the two parallel operated dewaxing
25 reactors can be operated such that the pour point of the resulting low and high viscous base oil grades are close to the desired values. Any pour point give away is indicative for yield loss of the grade having the lower than desired pour point.

30 Detailed description of the invention.

The feed to step (a) may be any typical feed to a hydrocracker. Such feedstocks may be the vacuum gas oil or heavier distillate fractions as obtained when
distilling at near vacuum conditions the atmospheric
35 residue of a crude mineral oil feedstock. The deasphalted

oil as obtained when deasphalting the residue as obtained in said vacuum distillation may also be used as feed.

Light and heavy cycle oils as obtained in a fluid catalytic cracking process (FCC), thermally flashed distillate and aromatic rich extracts as for example obtained in solvent extraction process steps in traditional base oil processing may also be used as feed. Mixtures of the above described feeds and optionally other hydrocarbon sources are also suitable as feedstocks. An optional alternative hydrocarbon source, which may be present in addition to the above feedstocks, preferably in amounts of between 2 and 30 wt% of the feed to step (a), are the paraffin wax as obtained in a Fischer-Tropsch process.

Step (a) may be performed at a conversion level of between 15 and 90 wt%. The conversion is expressed in the weight percentage of the fraction in the feed which boils above 370 °C which are converted to products boiling below 370 °C. The main products boiling below 370 °C are naphtha, kerosene and gas oil. Examples of possible hydrocracker processes suitable for performing step (a) are described in EP-A-699225, EP-A-649896, WO-A-9718278, EP-A-705321, EP-A-994173 and US-A-4851109.

The operating conditions of a single step hydrocracking process include preferably a temperature in the range of from 350 to 450 °C, a hydrogen pressures in the range of from 9 to 200 MPa, more preferably above 11 MPa, a weight hourly space velocities (WHSV) in the range of from 0.1 to 10 kg of oil per liter of catalyst per hour (kg/l/hr), preferably from 0.2 to 5 kg/l/hr, more preferably from 0.5 to 3 kg/l/hr and hydrogen to oil ratios in the range of from 100 to 2,000 liters of hydrogen per liter of oil.

Preferably the hydrocracker is operated in two steps, consisting of a preliminary hydrotreating step followed

by a hydrocracking step. In the hydrotreating step nitrogen and sulphur are significantly removed and aromatics are significantly saturated to naphthenes and part of the naphthenes are converted to paraffins by ring opening reactions. In order to improve the yield of the more viscous grade base oils the fuels-hydrocracker is more preferably operated by first (i) hydrotreating a hydrocarbon feed at a feed conversion, wherein the conversion, as defined above, of less than 30 wt% and preferably between 15 and 25 wt%, and (ii) hydrocracking the product of step (i) in the presence of a hydrocracking catalyst at such a conversion level that the overall conversion of step (i) and (ii) is between 15 and 90 wt% and preferably between 40 and 85 wt%.

The operating conditions of a hydrotreating step are preferably a temperature in the range of from 350 to 450 °C, a hydrogen pressures in the range of from 9 to 200 MPa, more preferably above 11 MPa, a weight hourly space velocities (WHSV) in the range of from 0.1 to 10 kg of oil per liter of catalyst per hour (kg/l/hr), preferably from 0.2 to 5 kg/l/hr, more preferably from 0.5 to 3 kg/l/hr and hydrogen to oil ratios in the range of from 100 to 2,000 liters of hydrogen per liter of oil.

The operating conditions of a hydrocracking step performed in combination with a hydrotreatings step are preferably a temperature in the range of from 300 to 450 °C, a hydrogen pressures in the range of from 9 to 200 MPa, more preferably above 11 MPa, a weight hourly space velocities (WHSV) in the range of from 0.1 to 10 kg of oil per liter of catalyst per hour (kg/l/hr), preferably from 0.2 to 5 kg/l/hr, more preferably from 0.5 to 3 kg/l/hr and hydrogen to oil ratios in the range of from 100 to 2,000 liters of hydrogen per liter of oil.

The full range residue as prepared by the processes as described above have a very low content of sulphur,

typically below 250 or even below 150 ppmw, and a very low content of nitrogen, typically below 30 ppmw.

5 It has been found that by performing the combined hydrotreating and hydrocracking step as described above a full range residue is obtained which yields a high quantity of the more viscous grade base oil, also referred to as medium machine oil grade, and of acceptable quality with respect to viscosity index. In addition a sufficient quantity of naphtha, kerosine and
10 gas oils are obtained by this process. Thus a fuels hydrocracker process is obtained wherein simultaneously products ranging from naphtha to gas oil and a full range residue is obtained, which full range residue has the potential to yield a medium machine oil base oil grade.
15 The viscosity index of the resulting base oil grades is suitably between 95 and 120, which is acceptable to yield base oils having a viscosity index according to the API Group II specifications.

20 It has been found that in the hydrotreating step (i) the viscosity index of the full range residue and the resulting base oil grades increases with the conversion in said hydrotreating step. By operating the hydrotreating step at high conversion levels of more than 30 wt% viscosity index values for the resulting base oils
25 of well above 120 can be achieved. A disadvantage of such a high conversion in step (i) is however that the yield of medium machine oil fraction will be undesirably low. By performing step (i) at the above described conversion levels an API Group II medium machine oil grade base oil
30 can be obtained in a desired quantity. The minimum conversion in step (i) will be determined by the desired viscosity index, of between 95 and 120, of the resulting base oil grades and the maximum conversion in step (i) is determined by the minimum acceptable yield of medium
35 machine oil grade.

The preliminary hydrotreating step is typically performed using catalyst and conditions as for example described in the above-mentioned publications related to hydrocracking. Suitable hydrotreating catalysts generally
5 comprise a metal hydrogenation component, suitably Group IVB or VIII metal, for example cobalt-molybdenum, nickel-molybdenum, on a porous support, for example silica-alumina or alumina. The hydrotreating catalysts suitably contains no zeolite material or a very low
10 content of less than 1 wt%. Examples of suitable hydrotreating catalysts are the commercial ICR 106, ICR 120 of Chevron Research and Technology Co.; 244, 411, DN-120, DN-180, DN-190 and DN-200 of Criterion Catalyst Co.; TK-555 and TK-565 of Haldor Topsoe A/S; HC-k, HC-P,
15 HC-R and HC-T of UOP; KF-742, KF-752, KF-846, KF-848 STARS and KF-849 of AKZO Nobel/Nippon Ketjen; and HR-438/448 of Procatalyse SA.

The hydrocracking step is preferably a catalyst comprising an acidic large pore size zeolite within a
20 porous support material with an added metal hydrogenation/dehydrogenation function. The metal having the hydrogenation/dehydrogenation function is preferably a Group VIII/Group VIB metal combination, for example nickel-molybdenum and nickel-tungsten. The support is
25 preferably a porous support, for example silica-alumina and alumina. It has been found that a minimum amount of zeolite is advantageously present in the catalyst in order to obtain a high yield of medium machine oil fraction in the full range residue when performing the
30 hydrocracker at the preferred conversion levels as explained above. Preferably more than 1 wt% of zeolite is present in the catalyst. Examples of suitable zeolites are zeolite X, Y, ZSM-3, ZSM-18, ZSM-20 and zeolite beta of which zeolite Y is most preferred. Examples of
35 suitable hydrocracking catalysts are the commercial

ICR 220 and ICR 142 of Chevron Research and Technology Co; Z-763, Z-863, Z-753, Z-703, Z-803, Z-733, Z-723, Z-673, Z-603 and Z-623 of Zeolist International; TK-931 of Haldor Topsoe A/S; DHC-32, DHC-41, HC-24, HC-26, HC-34 and HC-43 of UOP; KC2600/1, KC2602, KC2610, KC2702 and KC2710 of AKZO Nobel/Nippon Ketjen; and HYC 642 and HYC 652 of Procatalyse SA.

The effluent of the hydrocracker is separated into one or more of the above referred to fuels fractions and a full range residue. The full range residue, wherein the full range residue boils predominately above 340 °C, is used as feed to step (c). With boiling predominately above 340 °C is especially meant that more than 80 wt% boils above 340 °C. Because a substantial fraction of the full range residue may boil in the gas oil range a considerable amount of gas oil is recovered after dewaxing having excellent cold flow properties. Preferably between 10 and 40 wt% of the dewaxed oil as obtained in this process boils in the heavy gas oil range being between from 350 to 400 °C. It should of course be understood that also lower boiling gas oil fractions are obtained in step (c).

The final boiling point of the residue will be partly determined by the final boiling point of the feed to step (a) and may be far greater than 700 °C up to values of which cannot be determined by means of the standard test methods.

Optionally part of the residue as obtained in step (b) may be recycled to step (a) as for example described in EP-A-0994173, which publication is incorporated by reference. Optionally the residue may be recycled to only the hydrocracking step of step (a) as for example described in EP-B-0699225, which publication is incorporated by reference. Preferably less than 15 wt% of the full range residue is recycled to step (a) and

more preferably no residue is recycled to step (a). It has been found that API Group II base oils may be prepared having a good quality without having to perform such a recycle.

5 In step (c) the feed is separated by means of distillation into a light base oil precursor fraction and a heavy base oil precursor fraction and optionally a vacuum gas oil fraction. Preferably any vacuum gas oil is not separated from the light base oil precursor fraction
10 but remains combined with said fraction in order to be dewaxed as well in step (d). The distillation is suitably performed at reduced pressures, more preferably the vacuum distillation is performed at a pressure of between 0.01 and 0.3 bara. Preferably the 10 wt% recovery point
15 of the heavy base oil precursor fraction as obtained in step (c) is preferably between 420 and 550 °C and more preferably between 440 and 520 °C.

 The feed to step (d) will comprise of the base oil precursor fractions as obtained in step (c). Optionally
20 some partly isomerised paraffin wax boiling in the heavy or light base oil precursor fractions boiling range may be present in a mixture with said light base oil precursor fraction. This paraffin product is also referred to as waxy raffinate, as obtained in a Fischer-Tropsch or Gas-to-Liquids Process. Such a waxy Raffinate
25 may be prepared according the process as described in WO-02070630, which publication is incorporated herein by reference.

 Optionally a noble metal guard bed may be positioned
30 just upstream the dewaxing catalyst bed in the dewaxing reactor in step (d) in order to decrease the level of sulphur and especially nitrogen compounds. Such a guard bed may be especially advantageous in the dewaxing reactor in which the heavy base oil precursor fraction is
35 processed. An example of such a process is described in

WO-A-9802503, which reference is hereby incorporated by reference.

5 The catalytic dewaxing step in the parallel operated
reactors in step (d) can be performed by any process
wherein in the presence of a catalyst and hydrogen the
pour point of the base oil fraction is reduced. Suitably
the pour point is reduced by at least 10 °C and more
suitably by at least 20 °C. Suitable dewaxing catalysts
are heterogeneous catalysts comprising a molecular sieve
10 and optionally in combination with a metal having a
hydrogenation function, such as the Group VIII metals.
Molecular sieves, and more suitably intermediate pore
size zeolites, have shown a good catalytic ability to
reduce the pour point of a base oil fraction under
15 catalytic dewaxing conditions. Preferably the
intermediate pore size zeolites have a pore diameter of
between 0.35 and 0.8 nm. Suitable intermediate pore size
zeolites are ZSM-5, ZSM-12, ZSM-22, ZSM-23, SSZ-32,
ZSM-35 and ZSM-48. Another preferred group of molecular
20 sieves are the silica-aluminophosphate (SAPO) materials
of which SAPO-11 is most preferred as for example
described in US-A-4859311. ZSM-5 may optionally be used
in its HZSM-5 form in the absence of any Group VIII
metal. The other molecular sieves are preferably used in
25 combination with an added Group VIII metal. Suitable
Group VIII metals are nickel, cobalt, platinum and
palladium. Examples of possible combinations are
Ni/ZSM-5, Pt/ZSM-23, Pd/ZSM-23, Pt/ZSM-48 and Pt/SAPO-11.
Further details and examples of suitable molecular sieves
30 and dewaxing conditions are for example described in
WO-A-9718278, US-A-5053373, US-A-5252527 and
US-A-4574043.

35 The process according to the present invention makes it
possible to continuously prepare base oils using dewaxing
catalysts, which show a relatively large pour point

distribution in case the full range residue is processed as for example described in WO-A-9723584. By making use of the present invention such a large pour point distribution can be avoided while using such relatively poor performing dewaxing catalysts. An example of such a catalyst that shows a relatively large pour point distribution is the ZSM-5 based catalyst. Thus ZSM-5 based catalysts may be advantageously applied in the present invention. The process also makes it possible to use different dewaxing catalysts in the parallel-operated reactors, which catalyst can be more tailored to their respective feeds.

The dewaxing catalyst suitably also comprises a binder. The binder can be a synthetic or naturally occurring (inorganic) substance, for example clay, silica and/or metal oxides. Natural occurring clays are for example of the montmorillonite and kaolin families. The binder is preferably a porous binder material, for example a refractory oxide of which examples are: alumina, silica-alumina, silica-magnesia, silica-zirconia, silica-thoria, silica-beryllia, silica-titania as well as ternary compositions for example silica-alumina-thoria, silica-alumina-zirconia, silica-alumina-magnesia and silica-magnesia-zirconia. More preferably a low acidity refractory oxide binder material which is essentially free of alumina is used. Examples of these binder materials are silica, zirconia, titanium dioxide, germanium dioxide, boria and mixtures of two or more of these of which examples are listed above. The most preferred binder is silica.

A preferred class of dewaxing catalysts comprise intermediate zeolite crystallites as described above and a low acidity refractory oxide binder material which is essentially free of alumina as described above, wherein the surface of the aluminosilicate zeolite crystallites

has been modified by subjecting the aluminosilicate zeolite crystallites to a surface dealumination treatment. A preferred dealumination treatment is by contacting an extrudate of the binder and the zeolite with an aqueous solution of a fluorosilicate salt as described in for example US-A-5157191. Examples of suitable dewaxing catalysts as described above a silica bound and dealuminated Pt/ZSM-5 and silica bound and dealuminated Pt/ZSM-23, silica bound and dealuminated Pt/ZSM-12 and silica bound and dealuminated Pt/ZSM-22, as for example described in WO-A-200029511 and EP-B-832171.

Catalytic dewaxing conditions are known in the art and typically involve operating temperatures in the range of from 200 to 500 °C, suitably from 250 to 400 °C, hydrogen pressures in the range of from 10 to 200 bar, weight hourly space velocities (WHSV) in the range of from 0.1 to 10 kg of oil per litre of catalyst per hour (kg/l/hr), suitably from 0.2 to 5 kg/l/hr, more suitably from 0.5 to 4 kg/l/hr and hydrogen to oil ratios in the range of from 100 to 2,000 litres of hydrogen per litre of oil. The weight hourly space velocities (WHSV) in the catalytic dewaxing step in which the light base oil precursor fraction is processed is preferably higher than the WHSV in the dewaxing step of the heavy base oil precursor fraction. More preferably the WHSV in the dewaxing step of the light base oil precursor fraction is between 1 and 5 kg/l/hr.

If the dewaxing step and the hydrofinishing step are performed in cascade the pressure level in both steps is suitably of the same order. Because higher pressures are preferred in the hydrofinishing step in order to obtain a base oil having the desired properties the dewaxing step is suitably also performed at these higher pressures, even though a more selective dewaxing could have been

achieved at lower pressures. If no hydrofinishing step is required, as has been found to be the case for the dewaxed oil obtained from the light base oil precursor fraction to prepare for example the spindle oil base oil grade, a lower catalytic dewaxing pressure can be advantageously be applied. Suitable pressures are from 15 to 100 bar and more suitably from 1.5 to 6.5 MPa.

The hydrotreating step (e) also referred to as a hydrofinishing step is to improve the quality of the dewaxed fraction. In this step lube range olefins are saturated, heteroatoms and colour bodies are removed and if the pressure is high enough residual aromatics are saturated. Preferably the conditions are so chosen to obtain a base oil grade comprising more than 95 wt% saturates and more preferably such that a base oil is obtained comprising more than 98 wt% saturates. The hydrofinishing step is suitably carried out in cascade with the dewaxing step of the heavy base oil precursor fraction.

The hydrofinishing step is suitably carried out at a temperature between 230 and 380 °C, a total pressure of between 1 to 25 MPa and preferably above 10 MPa and more preferably between 12 and 25 MPa. The WHSV (Weight hourly space velocity) ranges from 0.3 to 10 kg of oil per litre of catalyst per hour (kg/l.h).

The hydrofinishing or hydrogenation catalyst is suitably a supported catalyst comprising a dispersed Group VIII metal. Possible Group VIII metals are cobalt, nickel, palladium and platinum. Cobalt and nickel containing catalysts may also comprise a Group VIB metal, suitably molybdenum and tungsten.

Suitable carrier or support materials are low acidity amorphous refractory oxides. Examples of suitable amorphous refractory oxides include inorganic oxides, such as alumina, silica, titania, zirconia, boria,

silica-alumina, fluorided alumina, fluorided silica-alumina and mixtures of two or more of these.

Suitable hydrogenation catalysts include those catalysts comprising as one or more of nickel (Ni) and cobalt (Co) in an amount of from 1 to 25 percent by weight (wt%), preferably 2 to 15 wt%, calculated as element relative to total weight of catalyst and as the Group VIB metal component one or more of in an amount of from 5 to 30 wt%, preferably 10 to 25 wt%, calculated as element relative to total weight of catalyst. Examples of suitable nickel-molybdenum containing catalyst are KF-847 and KF-8010 (AKZO Nobel) M-8-24 and M-8-25 (BASF), and C-424, DN-190, HDS-3 and HDS-4 (Criterion). Examples of suitable nickel-tungsten containing catalysts are NI-4342 and NI-4352 (Engelhard), C-454 (Criterion). Examples of suitable cobalt-molybdenum containing catalysts are KF-330 (AKZO-Nobel), HDS-22 (Criterion) and HPC-601 (Engelhard).

For hydrocracked feeds containing low amount of sulphur, as in the present invention, preferably platinum containing and more preferably platinum and palladium containing catalysts are used. The total amount of these noble Group VIII metal component(s) present on the catalyst is suitably from 0.1 to 10 wt%, preferably 0.2 to 5 wt%, which weight percentage indicates the amount of metal (calculated as element) relative to total weight of catalyst.

Preferred supports for these palladium and/or platinum containing catalysts are amorphous silica-alumina, whereby more preferably the silica-alumina comprises from 2 to 75 wt% of alumina. Examples of suitable silica-alumina carriers are disclosed in WO-A-9410263. A preferred catalyst comprises an alloy of palladium and platinum preferably supported on an amorphous silica-alumina carrier of which the

commercially available catalysts C-624 and C-654 of Criterion Catalyst Company (Houston, TX) are examples.

5 In step (f) the two or more base oil grades and optionally a gas oil comprising fraction are isolated from the light base oil precursor fraction from step (d) and the hydrotreated oil from step (e). The base oils and the optional gas oil comprising fraction are preferably isolated from a mixture of these streams. This is advantageous because any compounds present in the heavy
10 base oil precursor fraction which are converted in step (d) to a boiling range of a lighter base oil grade will then contribute to the base oil yield of said lighter base oil grade.

Because the gas oil product as obtained as described
15 above has been subjected to a catalytic dewaxing step a fuel product is obtained having a very low content of aromatics and sulphur in combination with excellent low temperature properties. Especially a gas oil may be obtained in step (d) having a very low sulphur content of
20 below 10 ppm, a low aromatics content of below 0.1 mmol/100 grams, excellent a cold flow properties like a pour point of below -30 °C and a cold filter plugging point of below -30 °C. The gas oil also has excellent lubricity properties. This makes such a gas oil
25 especially an excellent refinery blending component to blend low sulphur gas oil. The gas oil may also be used as a drilling mud fluid component, an electrical oil, a cutting oil, an aluminium rolling oil or as a fruit spray oil.

30 Step (f) may be performed by withdrawing products along a distillation column operating at near vacuum conditions as well known to the skilled person. Preferably so-called side-strippers are used to isolate the base oil products. Intermediate fractions may also be
35 withdrawn in order to meet the volatility requirements of

the desired base oil grades. Suitably before the above low pressure distillation step a higher pressure distillation step, at about atmospheric conditions, may be performed in order to separate any naphtha, kerosene and gas oil fractions, separately or as a mixture, from the dewaxed oil. These middle distillate fractions may be used as such or recycled to step (b) such that a mixture of dewaxed and hydrocracked middle distillate fuels are obtained. Thus in step (f) gaseous tops, a liquid tops comprising the above middle distillates, and various base oil grades, as for example a spindle oil, a light machine oil and a medium machine oil are obtained in the final distillation of step (f).

In the context of the present invention terms as spindle oil, light machine oil and medium machine oil will refer to base oil grades having an increasing kinematic viscosity at 100 °C and wherein the spindle oil additionally has a maximum volatility specification. The advantages of the present process are achieved for any group of base oils having such different viscosity requirement and volatility specification. Preferably a spindle oil is a light base oil product having a kinematic viscosity at 100 °C of below 5.5 cSt and preferably above 3.5. The spindle oil can have either a Noack volatility, as determined by the CEC L-40-T87 method, of preferably below 20% and more preferably below 18% or a flash point, as measured according to ASTM D93, of above 180 °C. Preferably the light machine oil has a kinematic viscosity at 100 °C of below 9 cSt and preferably above 6.5 cSt and more preferably between 8 and 9 cSt. Preferably the medium machine oil has a kinematic viscosity at 100 °C of below 14 cSt and preferably above 10 cSt and more preferably between 11 and 13 cSt. The corresponding base oil grade can have a viscosity index of between 95 and 120. Gas oil as

obtained in the process according the invention will boil typically from 150 and 370 °C and will have a T90wt% of between 340-400 °C.

5 The process of the present invention is further illustrated by Figure 1. figure 1 shows a hydrocarbon feed line (1) to hydrocracker (2). The hydrocrakate (3) is separated into a naphtha (5), kerosene (6), a gas oil (7) a bottoms fraction (8) in distillation column (4). The bottoms fraction or full range residue (4) is split into a light base oil precursor fraction (10) and a heavy base oil precursor fraction (11) in distillation column (9). The light base oil precursor fraction (10) is dewaxed in dewaxing reactor (12) yielding a dewaxed oil (16). The heavy base oil precursor fraction (11) is dewaxed in dewaxing reactor (13). The dewaxed oil (15) is hydrotreated in hydrofinishing reactor (14) yielding a dewaxed and hydrotreated oil (17). Oils (16) and (17) are combined. Hydrogen (19) is separated in separator (18) and recycled to the dewaxing units (12) and (13) after adding fresh hydrogen (20). The oil (21) is subsequently separated into a low boiling fraction (26), a spindle oil grade (23), a light machine oil grade (24) and a medium machine oil grade (25) is distillation column (22). The fraction (26) is recycled to the work-up section of the hydrocracker (2) in order to isolate the valuable fuels fractions.

C L A I M S

1. Process to prepare simultaneously two or more base oil grades and middle distillates from a de-asphalted oil or a vacuum distillate feed or their mixtures by performing the following steps:

- 5 (a) hydrocracking the feed,
- (b) distillation of the effluent as obtained in step (a) into one or more middle distillates and a full range residue boiling substantially above 340 °C,
- 10 (c) separating, by means of a further distillation step said full range residue into a light base oil precursor fraction and a heavy base oil precursor fraction,
- (d) reducing the pour point of each separate base oil precursor fraction in two simultaneously and
- 15 parallel operated catalytic dewaxing reactors,
- (e) hydrotreating the dewaxed oil as obtained when dewaxing the heavy base oil precursor fraction,
- (f) isolating from the dewaxed oil from the light base oil precursor fraction from step (d) and the
- 20 hydrotreated oil from step (e) two or more base oil grades.

2. Process according to claim 1, wherein the full range residue boils for more than 80 wt% above 340 °C and wherein the dewaxed oil as obtained in step (d) comprises

25 for between 10 and 40 wt% of a heavy gas oil range fraction boiling below 400 °C.

3. Process according to any one of claims 1-2, wherein between 20 and 40 wt% of the heavy base oil precursor fraction as obtained in step (c) is recycled to step (a).

30 4. Process according to any one of claims 1-3, wherein the 10 wt% recovery point of the heavy base oil precursor

fraction as obtained in step (c) is between 420 and 550 °C.

5 5. Process according to claim 4, wherein the 10 wt% recovery point of the heavy base oil precursor fraction as obtained in step (c) is between 440 and 520 °C.

10 6. Process according to any one of claims 1-5, wherein the feed to step (d) also comprises a partly isomerised paraffin wax as obtained in a Fischer-Tropsch process and boiling in the heavy and/or light base oil precursor fractions boiling range.

15 7. Process according to any one of claims 1-6, wherein the weight hourly space velocities in the catalytic dewaxing step (d) when processing the light base oil precursor fraction is higher than the WHSV in the dewaxing step (d) when processing the heavy base oil precursor fraction.

20 8. Process according to claim 7, wherein the WHSV when processing the light base oil precursor fraction is between 1 and 5 kg/l/hr.

25 9. Process according to any one of claims 1-8, wherein the pressure at which the light base oil precursor fraction is dewaxed in step (d) is between 15 and 65 bars and the pressure at which the heavy base oil precursor fraction is dewaxed is between 100 and 250 bars.

30 10. Process according to any one of claims 1-9, wherein step (f) is performed on a mixture of the dewaxed oil as obtained when processing the light base oil precursor fraction and the dewaxed and hydrotreated oil when processing the heavy base oil precursor fraction.

A B S T R A C T

PROCESS TO CONTINUOUSLY PREPARE TWO OR MORE BASE OIL
GRADES AND MIDDLE DISTILLATES

Process to prepare simultaneously two or more base oil grades and middle distillates from a de-asphalted oil or a vacuum distillate feed or their mixtures by performing the following steps:

- (a) hydrocracking the feed,
- (b) distillation of the effluent as obtained in step (a) into one or more middle distillates and a full range residue boiling substantially above 340 °C,
- (c) separating, by means of a further distillation step said full range residue into a light base oil precursor fraction and a heavy base oil precursor fraction,
- (d) reducing the pour point of each separate base oil precursor fraction in two simultaneously and parallel operated catalytic dewaxing reactors,
- (e) hydrotreating the dewaxed oil as obtained when dewaxing the heavy base oil precursor fraction,
- (f) isolating from the dewaxed oil from the light base oil precursor fraction from step (d) and the hydrotreated oil from step (e) two or more base oil grades.
